

Module Introduction Transcript

Hello everyone, welcome to module 12 of our course Statistical Inference and Modelling. So far, we have studied Maximum Likelihood Estimation and applied it to continuous outcomes. In this module, we will apply the principles of MLE to discrete response models.

These models are mainly logistic regression and these are used to study the association of dependent variables which are binary to different types of other variables, just like what we studied in multiple linear regression. In this module, these are the learning objectives. First, you will learn from linear probability model which is the simplest way of modelling binary outcomes.

Second, we will learn into the probability and logit models. These are standard statistical tools for binary response data. Third, you will learn how to interpret logit coefficients, calculate log of odds which will provide meaningful insights about decision making.

By the end of this module, we will be able to identify and apply the appropriate statistical techniques for binary data and you will be able to confidently interpret the results in real-world applications. So let's begin.
