

Module Introduction Transcript

Hello everyone, welcome to module 10 of our course statistical inference and modelling. So far, we have studied regression, time series, vector analysis, all of which focus on modelling relationships between variables. In this module, you turn into a new type of statistical method called clustering.

Clustering analysis is used to group data into meaningful segments or buckets, helping us to find patterns when no prior label exists. This module or module's learning objectives are as follows. First, you will learn how to process the data and find clusters.

Second, you will learn how to apply clustering algorithm using hierarchical clustering, k-means clustering and segment the data into various groups. Third, you will learn how to evaluate the number of clusters and interpret the results into meaningful ways. By the end of this module, you will be able to apply clustering methods to real-world datasets, identify natural groupings, and interpret them effectively and in various different situations.

So, let's begin.
