

Module Introduction Transcript

Hello everyone, welcome to module 4 of our course Statistical Inference and Modelling. In the last module, we studied estimation and hypothesis testing for a single population. We learned how to construct confidence intervals, determine sample sizes, and conduct one-sample hypothesis test.

In this module, we will extend those ideas to more complex situations, simplifying different scenarios, and then comparing various different types of populations. We will also introduce the concept of categorical data. These methods are very commonly used in real-world scenarios and in business world.

In this module, the learning objectives would be as follows. First, you will learn about how to make inferences about different population, two or more than two population means, or two or more population variants. Second, you will learn how to test equality of population proportions.

Third, you will learn how to use chi-square test for doing analysis on categorical datasets. By the end of this module, you will be confident in extending hypothesis testing from single populations to two populations to categorical variables. These methods will provide you practical tools that will be widely applicable across many domains.

Let's get started.
