

Module Introduction Transcript

Hello everyone, welcome to module 7 of our course Statistical Inference and Modelling. In the previous module, we studied simple linear regression, where a single predictor variable was used to explain or predict an outcome. But in many real-world scenarios, outcomes are influenced by several variables.

For example, house prices may depend on size, location, age of house, and so on. First, you will learn how to construct a multiple linear regression with several predictors. Second, you will learn how to evaluate the overall model fit using R-square.

Then, you will move into how to interpret multiple linear regression using various different types of things that we have. So, let's get started.
