

Module Introduction Transcript

Hello everyone, welcome to module 3 of our course Statistical Inference in Modelling. In this module, we will move beyond descriptive statistics and probability to focus on estimation and hypothesis testing. These are the tools that allow us to make inferences about populations using sample data.

The module learning objectives are as follows. The first, you will learn how to perform interval estimations for a population mean when the population variances are either known or unknown. Second, you will learn how to determine the right sample size for achieving a desired precision in estimation.

Third, you will learn how to formulate and conduct a full hypothesis testing. By the end of this module, you will be confident in applying estimation and hypothesis testing methods to real-world problems. In short, this module provides the essential foundations of inferential statistics.

Whether it is constructing confidence intervals or conducting hypothesis tests, these methods give us the power to draw meaningful conclusions from data. Let's begin with confidence interval in the next lesson.
